Abstract

First-principles based force fields developed from fitting to large quantum mechanical data sets are now the norm in predictive molecular dynamics simulations, as opposed to force fields fitted solely from phenomenological data. In principle, the former allow improved accuracy and transferability over a wider range of molecular compositions, interactions and environmental conditions unexplored by experiments. The trade-off has been force field engines that are functionally complex, with a large number of non-bonded and bonded analytical forms that give rise to enormous parameter search spaces. To address this problem, we have developed GARFfield[1], a parallel hybrid multi-objective Pareto-optimal parameter development scheme based on genetic algorithms, hill-climbing routines and conjugate-gradient minimization. Currently, GARFfield supports development of:

- ReaxFF reactive force fields[2],
- Effective core pseudo-potentials for electron force fields (eFF-ECP[3, 4]),
- Morse potentials for atomistic and coarse-grain force fields,
- COMB force fields[5],
- Tersoff force fields[6], and
- EAM force fields for alloys[7].

The flexible and open architecture of GARFfield enables cost-efficient optimization of parameters from first-principles data sets for any force field. Adding a new force field involves integrating the force field parser and only minor changes to the GARFfield core.

1 Introduction to GARFfield

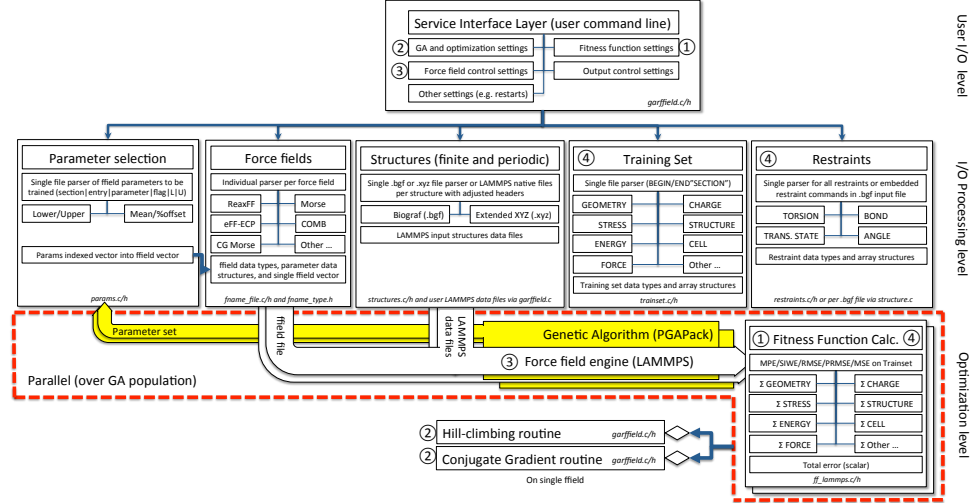

Figure 1: GARFfield’s software architecture. Circled numbers indicate connections 1-1, 2-2, 3-3, and 4-4 between functional blocks. Dotted block indicates all calculations performed in parallel, over the population size as *pop/procs*.

GARFfield’s computational core is written in ANSI C with a Message Passing Interface (MPI) for parallel computation support. GARFfield uses a modified PGAPack[8] library to produce a random population of the sub-set of force field parameters chosen by the user for optimization (see Parameter selection block in Fig. 1). This population is evaluated through library calls to the LAMMPS parallel molecular dynamics simulation code[9] (<http://lammps.sandia.gov>) based on a training set defined by the user (see Training set block in Fig. 1). The training set may contain different objective functions, and multiple entries per objective function, both of which can be weighted by the user. The referenced labels in the training set entries are used as index keys to the atomic or coarse-grain structure definition files, which are provided by the user or automatically generated by GARFfield in LAMMPS native format according to the force field being trained. Fitness and ranking values are produced, in parallel if desired, for every force field parameter set in the random population evaluated over the entire training set (see Fitness function, GA, and force field engines in Fig. 1). Based on a force field’s rank it is either used to evolve new siblings via mutation or crossover operations or discarded. The iterated population improves towards a higher-quality set of force fields, and upon convergence, the best performer is written to *ffield.best* along with the corresponding training set evaluation results in *trainset.err.best*. A hill-climbing routine may be used periodically to search for lower minima and a conjugate gradient method can

2. RUNNING GARFFIELD

be applied at the basin of a solution well to improve convergence speed. The LAMMPS library used by GARFfield is compiled to include the Reax/c[10] and eFF[11] user packages. It can be extended to support other force fields as required. Further details about GARFfield follow.

2 Running GARFfield

The general command line to run GARFfield is:

```
garffield <GeoFile> <ForceFieldFile> <TrainSetFile> <ParamsFile> [Options]
```

Where *GeoFile*, *ForceFieldFile*, *TrainSetFile* and *ParamsFile* correspond to the geometry file, force field parameter file, training set file, and the parameters selection file, respectively. These files can take any name as specified by the user, nevertheless they have a specific format (described in subsection 2). The optional arguments are:

Option	Arguments	Default	Description
GA			
-i	'range' or 'percent'	'range'	Parameter interval
-g	'GRGA' or 'eGRGA' or 'SSGA'	'SSGA'	Population replacement strategy
-m	[0:1.0]	1/numParams	Mutation rate
-o	[0:1.0]	0.85 (2-point)	Crossover rate
-p	[int]	100	Population size
-s	'maxiter' or 'nochange'	'maxiter'	Convergence criteria
-t	[int]	400	Maximum number of GA iterations
-x	<i>none</i>	Mutation only	Perform mutation and crossover operations
-z	[1-100]	10%	Percent replacement with SSGA
Other			
-c	<i>i</i>	No hillclimb	Hillclimb every <i>i</i> iterations
-C	[int]	off	Adjust size of mincap array in ReaxFF
-d	'full_debug' or 'lammmps_debug'	None	Debug verbosity
-e	'MPE' or 'SIWE' or 'RMSE' or		
-F	reax	Auto-detect	Use Fortran reaxFF engine
-f	<i>none</i>	Minimization	Use RMS force instead of minimization
-G	[int]	50	Switch to Conjugate Gradient after <i>i</i> iterations
-l	<i>LogFile</i> name	Console	Write log to <i>LogFile</i>
-I	[int]	500	Number of structure minimization steps
-M	'fire' or 'sd' or 'cg'	'cg'	Structure minimization method
-e	'NRMSE' or 'MSE'	'MPE'	Error function
-r	<i>j</i>	10	Report total error every <i>j</i> iterations
-R	<i>k</i>	50	Restart every <i>k</i> GA iterations
-S	[double]	1.6	Safezone array allocation factor
-u	'real'	electron units (eFF-ECP)	Force units to be real
-v	<i>none</i>	off	Use low-gradient vdW correction in reax/c
-W	<i>none</i>	off	Randomize objective function weights
-w	<i>BestForceFieldFile</i> name	off	Write <i>BestForceFieldFile</i> every <i>j</i> iterations

Table 1: Command line options in GARFfield

Where GRGA corresponds to Generational (i.e. all strings) and SSGA to a steady-state replacement strategy, MPE is Mean Percent Error, SIWE is Sum Inverse Weighted Error, RMSE is Root Mean Square Error, NRMSE is the Normalized RMSE, and MSE is Mean Squared Error.

Note that using the low-gradient dispersion correction in ReaxFF force fields (-v option in GARFfield) requires additional parameters (33-34) in the atom section and an additional parameter (7) in the off-diagonal section of ReaxFF force field file.

To run GARFfield in single processor mode with the default settings, issue the following command line:

```
garffield <GeoFile> <ForceFieldFile> <TrainSetFile> <ParamsFile>
```

2. RUNNING GARFFIELD

To run over multiple processors, issue:

```
mpirun -n p garffield <GeoFile> <ForceFieldFile> ...  
<TrainSetFile> <ParamsFile> [Options]
```

Where *p* is the number of processes spawned within the Message Passing Interface (MPI) environment. GARFfield uses a modified version of pgapack [8] that creates an initial random population of force field parameter sets of size *pop* and parallelizes its evaluation using the selected force field type over the number of desired MPI processes, hence, $p \leq pop$. The parallel implementation uses a *master-slave* setup that varies with the number of processes. When two processors are used, both the *master* and the *slave* compute function evaluations. When more than two processors are used, the *master* is responsible for bookkeeping only, and the *slaves* take care of the function evaluations.

1 Setting GARFfield’s evolutionary algorithm optimizer

GARFfield uses real-valued strings to represent the force fields, or GA chromosomes. The GA selection process by which it allocates reproductive trials to force fields on the basis of their fitness, is done using the tournament selection method. The crossover operators that take bits from parent force fields and combines them to create sibling force fields is set to two-point crossover at a rate of 0.85. The option *-o* may be used to change the crossover rate. It is set to undergo mutation with a uniform probability (between 0-1) that defaults to the reciprocal of the string length, i.e. the number of force field parameters being optimized. If the allele values generated by mutation fall outside of the initial range of a particular gene, then it is reset to the lower value of the initialization range defined in the *ParamsFile*.

2 GARFfield’s input files

The following input files are required:

- *GeoFile*. A single ASCII file containing all the molecular structure definition files in sequence, separated by a blank line. Supported formats are biograft (.bgf) (see http://www.chem.cmu.edu/courses/09-560/docs/msi/modenv/D_Files.html#944609) or extended .xyz (see <https://camtools.cam.ac.uk/wiki/site/5b59f819-0806-4a4d-0046-bcad6b9ac70f/extendedxyz.html>). Alternatively, the user can provide a local LAMMPS format molecular data structure file for every geometry called within the training file, in which case no *geofile* needs to be provided. The latter is required for the *eff* force field because the explicit electron properties (i.e. radius and spin) are only described in the LAMMPS definition[11]. In this particular case, the user must also specify in each LAMMPS molecular structure file header the atom *number:name* pairs, where *number*=1..*n*, and any boundary conditions as follows:

```
ECP opt: 1 AtomName1 2 AtomName2 ... n AtomNamen
```

2. RUNNING GARFFIELD

for finite systems, and

```
ECP opt: 1 AtomName1 2 AtomName2 ... n AtomNamen: periodic
```

for periodic systems.

Triclinic cells are automatically converted to comply with LAMMPS' triclinic basis (see http://lammps.sandia.gov/doc/Section_howto.html#howto-12) for both xyz and bgf structure file input formats. By default, GARFfield allows large box tilts.

- *ForceFieldFile*. Force field parameter file parsers are included for: ReaxFF[2], eFF-ECP[3, 11], COMB[5], Morse for atomistic and coarse-grain systems, Tersoff[6], and EAM[7]¹. Adding support for other force fields is straightforward, requiring a corresponding parser (source and header files) and force field header file to define any new data types. The force field engine used to calculate the fitness of each parameter set is automatically detected from the force field file header definition (see below), except in the case of ReaxFF. Currently, LAMMPS[9] is used to compute the different energy/force evaluations in GARFfield. There are two versions of ReaxFF in LAMMPS, a Fortran version and a C version[10], and GARFfield supports both. By default, the C version is used for all reaxFF force field optimizations, but the user can switch to the Fortran version using the option "-F reax" in the command line. For GARFfield to detect either of the ReaxFF implementations, the force field header file needs to start with the word "Reactive".

The eFF-ECP force field format for the s , p and hybrid $s - p$ potential functional forms is specified as:

```
eFF-ECP
n
AtomName1 ECtype1 ECPradius1 a1 b1 c1 d1 e1
AtomName2 ECtype2 ECPradius2 a2 b2 c2 d2 e2
:
AtomNamen ECtypen ECPradiusn an bn cn dn en
```

Where n is an integer corresponding to the number of ECP entries in the force field, AtomName _{i} corresponds to the name of atom i , ECtype _{i} to the type of ECP used (i.e. s , p , h [hybrid] or x [pseudopotential] as described in [12]) for atom i , ECPradius _{i} to the core radius of atom i , and $a - e$ to the parameters in the corresponding type of ECP. There should be one AtomName definition line per ECP entry in the force field, i.e. $i = 1..n$ in total.

The eFF-ECP force field format for the angular momentum projection operator, s, p, d , or up to f , is specified as:

¹Tersoff and EAM parsers were added by Dr. Anurag Chaudhry

2. RUNNING GARFFIELD

eFF-ECP

n

AtomName₁ s p₁ p₂ p₃ p₄

AtomName₂ p p₁ p₂ p₃ p₄ p₅ p₆

AtomName₃ d p₁ p₂ p₃ p₄ p₅ p₆ p₇ p₈

AtomName _{n} f p₁ p₂ p₃ p₄ p₅ p₆ p₇ p₈ p₉ p₁₀

Where n is an integer corresponding to the number of ECP entries in the force field, AtomName _{i} corresponds to the name of atom i , ECPTyp _{i} to the type of ECP used (i.e. with s , p , d , or f angular momentum projections[12]) for atom i , and p_i to the parameters in the corresponding type of ECP; first two are global angular projections and two additional parameters per each level of projection (i.e. 2 for s , 2 for p , 2 for d , and 2 for f). There should be one AtomName definition line per ECP entry in the force field, i.e. $i = 1..n$ in total.

The Morse format as:

Morse

n atom types

AtomName₁ AtomMass₁

AtomName₂ AtomMass₂

:

AtomName _{n} AtomMass _{n}

m pair types

AtomName₁ AtomName₁ D₀ α r₀

AtomName₁ AtomName₂ D₀ α r₀

:

AtomName _{n} AtomName _{n} 0 α r₀

Where n and m are integers ($m \leq 2^n$), AtomName _{i} corresponds to the name of atom i , and AtomMass _{i} to the mass of atom i .

The Tersoff format as:

Tersoff

Element₁ Element₂ Element₃ m gamma lambda₃ c d costheta0 n

beta lambda₂ B R D lambda₁ A

Where Element₁ corresponds to the center atom in a 3-body interaction, Element₂ to the atom bonded to the center atom, and Element₃ to the atom influencing the 1-2 bond in a bond-order sense. n , beta, lambda₃ (1/distance units), B (energy units), lambda₂ (1/distance units), and A

2. RUNNING GARFFIELD

(energy units) parameters are only used for two-body interactions. The m , γ , λ_3 , c , d , and $\cos\theta_0$ (can be a value ≤ -1 or ≥ 1) parameters are only used for 3-body interactions. The R (distance units) and D (distance units) parameters are used for both 2-body and 3-body interactions. The non-annotated parameters are unitless. The value of m must be 3 or 1.

For a single-element simulation, only a single entry is required (e.g. Si Si Si). For a two-element simulation, the file must contain 8 entries (for Si Si Si, Si Si C, Si C Si, Si C C, C Si Si, C Si C, C C Si, C C C), that specify Tersoff parameters for all permutations of the two elements interacting in 3-body configurations. Thus for 3 elements, 27 entries would be required, etc. The Tersoff force field parsing code in GARFfield supports multiple elements, however it does not check completeness (this is left to the user). See http://lammps.sandia.gov/doc/pair_tersoff.html for more information.

The COMB potential file format corresponds to the one used in LAMMPS (http://lammps.sandia.gov/doc/pair_comb.html).

The support for EAM potentials is a very specific implementation developed by Zhou et al[7]. In this flavor of EAM, there are 20 different parameters which are specified in the *ffield* file, as follows:

Zhou_EAM

```
Element1 Element2 Element3 re2 fe ρe ρs α β A B κ λ Fn0 Fn1 ...  
Fn2 Fn3 F0 F1 F2 F3 η Fe
```

Please refer to Table III in Ref.[7] for the names of these parameters and equations A1-A8 for the corresponding analytical forms of embedding energy, density and pair potential functions formed using these 20 elements. The referenced table gives a set of EAM parameters for 16 different metals. Thus the 20 values in the *ffield file* used in GARFfield for the Zhou EAM potential should correspond to those above. At present GARFfield supports only single element parameter optimization.

- *TrainSetFile*. A diverse set of cases computed from quantum mechanics and used by GARFfield to calculate the fitness of a particular parameter set. This file may contain a single or a combination of objective function sections, in the following format:

```
CHARGE <weight>  
#Key weight Atom Charge (a,f,i)  
ENDCHARGE  
STRESS <weight>  
#Key weight xx[yy zz xy xz yz] (a,f,a)  
ENDSTRESS
```

2. RUNNING GARFFIELD

```
PRESSURE <weight>
#Key weight press|xx|yy|zz|xy|xz|yz Value (a,f,a,f)
ENDPRESS
STSTRAIN <weight>
#Key weight xx Value [yy Value zz Value xy Value xz Value yz Value] (a,f,a,f[a,f])
ENDSTSTRAIN
ATOM_FORCE
#Key weight Atom1 fx, fy, fz (a,f,i,f,f,f)
ENDATOM_FORCE
CELL PARAMETERS <weight>
#Key weight a[b,c] Value (a,f,a,f)
ENDCELL_PARAMETERS
FREQUENCIES <weight>
#Key WeighF WeighM QM file
ENDFREQUENCIES
HEATFO <weight>
#Key weight Value (a,f,f)
ENDHEATFO
GEOMETRY <weight>
#Key weight Atom1 Atom2 Atom3 Atom4 Value (a,f,i,i,(i,i),f)
ENDGEOMETRY
STRUCTURE <weight>
#Key weight Atom1 Atom2 Value (a,f,i,i,f)
ENDSTRUCTURE
ENERGY <weight>
#weight op1 Key1 / n1 op2 Key2 / n2 op3 Key3 / n3 op4 Key4 / n4 ...
opn Keyn / nn Value (f,(a,a,i),f)
ENDENERGY
```

Where, *Key* corresponds to the structure file name specified in *GeoFile* or LAMMPS data.*Key* files, *weight* is the scalar multiplier used for each section or each entry when computing the weighted sum in the total error, *op* are mathematical + or - operators and *Value* is the literal reference value from quantum mechanical calculations or experiments. The section weight will default to 1 when not entered directly by the user or randomly generated by GARFfield (with the "-W" option).

With the exception of eFF-ECP training, which uses 'electron' units, all others use units of length in Angstroms, units of energy in kcal/mol, units of force in kcal/mol-Angstrom, and units of charge in multiples of electron charge. Electron units are length in Bohr, energies in eV, forces in Hartrees/Bohr, and charges in multiples of electron charge. The user can force eFF-ECP optimization using real units by the command line argument "-u real". This requires all molecular structure files and training set to be defined in the chosen units (i.e. GARFfield will not perform automatic conversion of units for user-specified data).

2. RUNNING GARFFIELD

The letters in parenthesis are meant to indicate the data type for each entry, i.e. i=integer, f=real, a=ASCII, and should not be part of the actual entry. Those within () denote possible repeating entries.

The **CHARGE** section is used to optimize atomic charge equilibration parameters for reaxFF, including electronegativity, hardness and radius.

The **STRESS** section is used to optimize force field parameters against a periodic unit cell with no stress.

The **PRESSURE** section is used to optimize force field parameters against a periodic unit cell scalar or pressure tensor components.

The **STSTRAIN** section is used to optimize force field parameters against a particular set of stress tensor components, i.e. principal components (xx,yy,zz) and products (xy,xz,yz). Only one weight is used for all components of the tensor.

The **ATOM_FORCE** section is used to optimize force field parameters against atomic forces (fx,fy,fz). This usually improves the accuracy and transferability of a force field, i.e. by adding energy gradients.

The **CELL_PARAMETERS** section is used to optimize force field parameters against periodic unit cell lattice parameters.

The **GEOMETRY** section is used to optimize force field parameters against geometrical features such as bond lengths, angles, and torsions.

The **STRUCTURE** section is currently supported (only) for radial distribution functions (RDF) used in training coarse-grain Morse force fields.

The **ENERGY** section is used to optimize force field parameters against energy *differences*.

- *ParamsFile*. Determines what parameters will be optimized by GARFfield. The file has a columnar format, with every row entry as follows:

Section Entry Parameter 0.0 Low High (i,i,i,f,f,f)

Where the Parameter from Entry in Section has an optimization range between Low and High, when the command line option "-i range" is used. Alternatively, when a starting force field with acceptable values is available to the user, such values may be used as a mean from which GARFfield can explore with a \pm percent offset, using the command line option "-i percent." The file format must then be given as:

Section Entry Parameter 2.0 Mean %Offset (i,i,i,f,f,f)

Where *Mean* is taken directly from the *ForceFieldFile* and the % offset is taken from the *ParamsFile*. The first number in column 4 should be ≤ 2.0 .

2. RUNNING GARFFIELD

- *RestraintFile*. For training reactive force fields it is useful to include information about the reactants, the products, and the transition states. Since GARFfield performs geometry minimization with the selected force field engine, restraints must be applied to avoid structural deviations from the desired reaction pathway/coordinate. These restraints may be applied on relative distances between 2 atoms, angles between 3 atoms and torsions between 4 atoms. The format for defining such restraints in the *RestraintFile* is:

RESTRAINT Key Keyword args

Where,

Key = name of structure file in *GeoFile*

keyword = *BOND* or *ANGLE* or *TORSION*

BOND args = *particle*₁ *particle*₂ *K*_{start} *K*_{stop} *r*₀

*particle*₁, *particle*₂ = IDs of 2 particles in bond

*K*_{start}, *K*_{stop} = start/end restraint coefficients (energy units)

*r*₀ = equilibrium bond distance (distance units)

ANGLE args = *particle*₁ *particle*₂ *particle*₃ *K*_{start} *K*_{stop} *θ*₀

*particle*₁, *particle*₂, *particle*₃ = 3 particle IDs in angle,

*particle*₂ = middle particle

*K*_{start}, *K*_{stop} = start/end restraint coefficients (energy units)

*θ*₀ = equilibrium angle (degrees)

TORSION args = *particle*₁ *particle*₂ *particle*₃ *particle*₄ *K*_{start} *K*_{stop} *φ*₀

*particle*₁, *particle*₂, *particle*₃, *particle*₄ = 4 particle IDs in dihedral (linear)

*K*_{start}, *K*_{stop} = start/end restraint coefficients (energy units)

*φ*₀ = equilibrium dihedral angle phi (degrees)

GARFfield will automatically detect and use a *RestraintFile* as its 5th argument in the command line. When using a biograf (.bgf) format *GeoFile* the user can describe the restraints directly in each structure definition via the keyword RESTRIN, thereby avoiding the need for a separate *RestraintFile*.

A particle in the nomenclature used above for GARFfield can be an actual atom, an electron, or a bead representing a group of particles (e.g. for coarse-grain force fields).

3 GARFfield's output files

When GARFfield starts, it outputs to the console: 1) the default settings and any changes made to these by the user, and the general details of 3) the *Force-*

3. GARFFIELD'S PARALLEL PERFORMANCE

FieldFile read, 4) the *GeoFile*, 5) the *TrainSetFile*, and 5) the *ParamsFile* before starting the optimization process and outputting the total error per iteration. In addition to this, there are other types of output from GARFfield, including:

- *Force field parameters.* A *ffield.best* file containing the best set of parameters found during the optimization is produced at the end of every run. This file has the same format as the input *ForceFieldFile*. A file *ForceFieldFile.original* corresponding to the starting force field is written at the start of the program, and an intermediate *ffield.new* file corresponding to the current iteration force field file is written every GA iteration. If the option *-w* is used, a *ffield.restart* file corresponding to the best string evaluated up to the last GA reported iteration is also written (the restart frequency is controlled by the *-r* option value).
- *Error information.* A *trainset.err.best* file is written with the error values obtained from the evaluation of *TrainSetFile* with *ffield.best*. A *trainset.err.initial* file is written with the error values obtained from the evaluation of *TrainSetFile* with the *ForceFieldFile.original* file. The files follow the format of the original *TrainSetFile*, except that additional columns are included for the force field values, the calculated weighted error figure for every entry, and the total accumulated weighted error.
- *Debug information.* There are two levels of debug verbosity written by GARFfield to the console (or a *logfile* when using the *-l* command line option), as controlled by the *-d* option in the command line (see Table 2). These are written only for process 0.
- *Restart.* Two restart options are provided in GARFfield: 1) a periodic restart using the *-R* option produces a new population reseeded from the best accumulated force field (i.e. mutated variants of the seed, with mutation probability at 0.5), and 2) the *-w BestForceField* option to periodically write out the best accumulated force field, which can then be used as input to restart an optimization run. Option 2 is useful for large runs that require restarts (e.g. queued systems), and option 1 is recommended when the initial force field corresponds to a reasonably good set of parameters (setting the restart frequency to a large number).

Additional intermediate files are generated for parallel runs; all of which are cleaned on exit.

3 GARFfield's parallel performance

The speedup from using multiple processors will vary with the amount of computation associated with the function evaluation (i.e. the size and complexity of the training set), the ratio between the GA population size (controlled using the *p* option in the command line) and the number of processors available

3. GARFFIELD'S PARALLEL PERFORMANCE

Figure 2: Speedup for ReaxFF SiC parameter set optimization under Los Alamos' National Laboratory supercomputer Mapache.

for the computation, the number of population strings created each GA generation (i.e. the replacement policy), and the communication/synchronization overheads associated with distributing and collecting information to and from the *slaves*. For example, when using two processors, if the population size is 100 and 100 new strings are created each GA generation, then 101 processors can be used effectively to run the (1) master and (100) slaves processes. However, the default setting (SSGA) only replaces 10% of the population each GA iteration, hence only 10 processors can be effectively used to maximize the degree of parallelism. The percent replacement can be modified using the option (-z). Depending on the computer architecture used to run GARFfield, significant non-linear speedup can be achieved from the use of cache hierarchies (see Figure 2).

4 Acknowledgements

Thanks to Dr. Anurag Chaudhry for his force field extensions to support Tersoff and EAM/alloys with GARFfield.
